

yeast apparently has a surface tension of about 0.60. The article seems to clear away much of the haze that has surrounded the matter of the significance of surface tension in cell activity.—WILLIAM CROCKER.

Underground organs of weeds.—Conflicting statements by various authors have induced PAMMEL and FOGEL²³ to investigate the organs of vegetative reproduction of some of our most common weeds. The Canada thistle (*Cirsium arvense*), the horse nettle (*Solanum carolinense*), the milkweed (*Asclepias syriaca*), and the bindweed (*Convolvulus arvensis*), were all found to be propagated by horizontal roots bearing adventitious buds; while in the wild morning glory (*Convolvulus Sepium*) and the quack grass (*Agropyron repens*), the organs of vegetative multiplication are rootstocks. In some instances the roots and subterranean stems resembled each other so closely that only by microscopic examination could the difference be detected.—GEO. D. FULLER.

Epidermis and light refraction.—FRIMMEL²⁴ thinks he has shown that the lower papillate epidermis of the leaves of the yew gives a total refraction of the light passing through the leaf from above, thereby leading to the use of all light that enters the leaf. He relates this character to the ability of the tree to grow in shaded habitats. He believes the lower epidermis of a number of other conifers acts in the same way. He finds a similar contrivance in the spongy parenchyma of the cotyledon of the beech. The fact of total refraction in the yew seems entirely established; whether it is of biological significance or not is quite another question.—WILLIAM CROCKER.

Arctic vegetation.—Hare Island off the coast of West Greenland, an uninhabited island 66 square miles in area, has been visited several times by PORSILD,²⁵ who has found a flora consisting of 82 arctic and 30 subarctic species. The vegetation belongs to the fell-field formation, large areas quite devoid of plants, passing into a poorly developed heath with arctic meadows and bogs in the more sheltered situations. Dispersal is almost entirely through the agency of the wind over the surface of the snow and frozen seas. The subarctic species are regarded as relics of milder climate in post-glacial times.—GEO. D. FULLER.

Pneumatophores.—From an examination of the tissues of vertical apogeo-tropic branches of the roots of *Terminalia Arjuna*, a large tree of Central India,
